To investigate the ability of human dendritic cells (DC) to process AΒ and present multiple epitopes from the gp100 melanoma tumor-assocd. Ags (TAA), DC from melanoma patients expressing HLA-A2 and HLA-A3 were pulsed with gp100-derived peptides G9154, G9209, or G9280 or were infected with a vaccinia vector (Vac-Pmel/gp100) contg. the gene for gp100 and used to elicit CTL from autologous PBL. CTL were also generated after stimulation of PBL with autologous tumor. CTL induced with autologous tumor stimulation demonstrated HLA-A2-restricted, qp100-specific lysis of autologous and allogeneic tumors and no lysis of HLA-A3-expressing, gp100+ target cells. CTL generated by G9154, G9209, or G9280 peptide-pulsed, DC-lysed, HLA-A2-matched EBV transformed B cells pulsed with the corresponding peptide. CTL generated by Vac-Pmel/gp100-infected DC (DC/Pmel) lysed HLA-A2- or HLA-A3-matched B cell lines pulsed with the HLA-A2-restricted G9154, G9209, or G9280 or with the HLA-A3-restricted G917 peptide derived from gp100. Furthermore, these DC/Pmel-induced CTL demonstrated potent cytotoxicity against allogeneic HLA-A2- or HLA-A3-matched gp100+ melanoma cells and autologous tumor. The authors conclude that DC-expressing TAA present multiple gp100 epitopes in the context of multiple HLA class I-restricting alleles and elicit CTL that recognize multiple qp100-derived peptides in the context of multiple HLA class I alleles. The data suggest that for tumor immunotherapy, genetically modified DC that express an entire TAA may present the full array of possible CTL epitopes in the context of all possible HLA alleles and may be superior to DC pulsed with limited nos. of defined peptides.

The present invention relates to isolation of cytotoxic T lymphocyte AB (CTL) clones. In particular, the present invention relates to isolated CTL clones that are specific for proteins of the MAGE family. The CTL clones of the present invention have been isolated by successive steps of stimulation and testing of lymphocytes with antigen presenting cells which present antigens derived from different expression systems, e.g., from recombinant Yersinia , recombinant Salmonella , or recombinant viruses. The present invention further relates to antigenic peptides as well as the peptide/HLA complexes which are recognized by the isolated CTL clones.

A tumor rejection antigen encoded by an alternative open reading AB frame of the macrophage colony stimulating factor gene that is expressed in renal cell carcinoma is identified and characterized. The antigen can be used in the diagnosis, prophylaxis and treatment of renal cell carcinoma. The antigen was identified as one recognized by cytotoxic T-lymphocytes and a cDNA was cloned by screening an expression library in 293-EBNA cells using cells expressing HLA-B\*3501 and HLA-Cw\*0401 genes from the cytotoxic T-lymphocytes. Sequencing of the cDNA showed that it was derived from a splice variant of the macrophage colony-stimulating factor transcript. AN HLA-B35-binding peptide of the antigen was The antigen was found in normal renal tubular cells and identified. hepatocytes but not in other major tissues tested. Expression was regulated independently from that of macrophage colony-stimulating factor.

Several HLA-A\*0201-restricted peptide epitopes that can be used as targets for active immunotherapy have been identified within melanocyte differentiation proteins. However, uncertainty exists as to the most effective way to elicit CD8+ T cells with these epitopes in vivo. The authors report the use of transgenic mice expressing a deriv. of HLA-A $\star$ 0201, and dendritic cells, to enhance the activation of CD8+ T cells that recognize peptide epitopes derived from human

tyrosinase and glycoprotein 100. The authors find that by altering the cell surface d. of the immunizing peptide on the dendritic cells, either by pulsing with higher concns. of peptide, or by changing the MHC-peptide-binding affinity by generating variants of the parent peptides, the size of the activated CD8+ T cell populations can be modulated in vivo. Significantly, the d. of peptide that produced the largest response was less than the max. d. achievable through short-term peptide pulsing. The authors have also found, however, that while some variant peptides are effective at eliciting both primary and recall CD8+ T cell responses that can recognize the parental epitope, other variant epitopes lead to the outgrowth of CD8+ T cells that only recognize the variant. HLA-A\*0201 transgenic mice provide an important model to define which peptide variants are most likely to stimulate CD8+ T cell populations that recognize the parental, melanoma-specific peptide. 162558-08-9

AB The invention describes HERV-AVL3-B tumor assocd. genes, including fragments and biol. functional variants thereof. Also included are polypeptides and fragments thereof encoded by such genes, and antibodies relating thereto. Methods and products also are provided

for diagnosing and treating conditions characterized by expression of a HERV-AVL3-B gene product.

AR When mixts. of peptides in multivalent vaccines are used, a key question is whether the peptides with a higher affinity for binding to the MHC will competitively block MHC binding of other peptides below the threshold necessary for T cell recognition. Here, a high-affinity peptide epitope for melanoma-reactive cytotoxic T cells (gp10054-162) and a high affinity peptide epitope for flu-reactive CTLs (influenza M158-66) were combined and these peptides were pulsed at various ratios onto antigen-presenting cells. At equimolar concns. of high-affinity peptides, no blocking of T cell recognition could be seen. Only with a 100-fold excess of M1 was the response to melanoma-reactive CTLs to gp100-peptide reduced. These data suggest that the use of mixts. of peptide in peptide-based vaccines may not cause significant competitive inhibition of MHC binding as long as the peptides are used at equimolar concns.

H-2 class I-neq., HLA-A2.1-transgenic HHD mice were used for a AΒ comparative evaluation of the immunogenicity of HLA-A2.1-restricted human tumor-assocd. cytotoxic T lymphocyte (CTL) epitopes. A hierarchy was established among these peptides injected into mice in incomplete Freund's adjuvant which correlates globally with their capacity to bind and stabilize HLA-A2.1 mols. Co-injection of a helper peptide enhanced most CTL responses. In contrast, classical HLA class I-transgenic mice which still express their own class I mols. did not, in most cases, develop HLA-A2.1-restricted CTL responses under the same exptl. conditions. Different monoepitope immunization strategies of acceptable clin. usage were compared in HHD mice. Recombinant Ty-virus-like particles, or DNA encoding epitopes fused to the hepatitis B virus middle envelope protein gave the best results. Using this latter approach and a melanoma-based polyepitope construct, CTL responses against 5 distinct epitopes could be elicited simultaneously in a single animal. Thus, HHD mice provide a versatile animal model for preclin. evaluation of peptide-based cancer immunotherapy.

 Genes encoding tumor rejection antigen precursors SAGE (sdph3.10),
 sdp3.5 and HAGE (sdp3.8) are cloned and their products characterized
 for therapeutic use. Methods and products also are provided for
 diagnosing and treating conditions characterized by expression of
 sdph3.10, sdp3.5 and/or sdp3.8 gene products. Genes specific to a
 sarcoma were identified by representational difference anal. Many
 were found to be genes normally assocd. with cell proliferation, and
 of the remainder, three showed ectopic expression in tumors, i.e.
 were expressed in a tumor, not in the corresponding normal tissue,
 but were expressed in other normal tissues. The genes showed normal
 expression in tissues of the reproductive system (uterus, mammary
 gland, testis) and skin.

immunotherapy. Here the authors describe a recombinant poxvirus vaccine that codes for 10 HLA-A2-restricted epitopes derived from 5 melanoma Ags conjoined in an artificial polyepitope or polytope construct. Target cells infected with the melanoma polytope vaccinia were recognized by 3 different epitope-specific CTL lines derived from HLA-A2 melanoma patients, and CTL responses to 7 of the epitopes were generated in at least one of 6 HLA-A2-transgenic mice immunized with the construct. CTL lines derived from vaccinated transgenic mice were also able to kill melanoma cells in vitro. Multiple epitopes within the polytope construct were therefore shown to be individually immunogenic, illustrating the feasibility of the polytope approach for melanoma immunotherapy. Tumor escape from CTL surveillance, through down regulation of individual tumor Ags and MHC alleles, might be overcome by polytope vaccines, which simultaneously target multiple cancer Ags.

WO 1999-US6031 W 19990319 The present invention provides compns. and methods for improved AB immunotherapy and cancer vaccine, and in particular for inducing an immune response against an antigen in a patient. Thus, in one aspect, this invention provides genetically modified antigen-presenting cells which are more potent presenters of exogenous peptide than parental antigen-presenting cells. Compns. comprising these genetically modified cells and a carrier, such as pharmaceutically acceptable carrier, are further provided by this invention. The genetically modified antigen-presenting cells of this invention can be used in adoptive immunotherapy or to expand a substantially pure population of immune effector cells. Methods for expansion of the substantially pure population of cells are also provided by this invention. Described were cytotoxic T cell epitopes of HSV-1 and HSV-2 ICP47 peptides, melanoma antigen gp100 and MART1, and human tyrosinase-related protein 2.

The induction of an in vitro T cell response against tumor-assocd. antigens with subsequent expansion of the individual cytotoxic T lymphocyte (CTL) clones still is not routine and the only tumor-assocd, antigen that has been found to easily induce the establishment of CTL clones is the MART-1/Melan-A antigen. In this paper, we describe a new approach for in vitro immunization based on the use of preselected melanoma cell clones. The human melanoma cell subline FM3.P was cloned and the immunol. properties of individual clones were compared. Melanoma cell clone FM3.29, having a high level of expression of melanoma differentiation antigens, as well as high levels of the HLA class I and class II antigens and adhesion mols., was used for the establishment of a CTL line that was subsequently cloned. For optimization of the conditions of growth of established CTL clones, a particular melanoma subline FM3.D/40 was selected for supporting the proliferation of CTL The majority of the established CTL clones recognized the melanoma-assocd. differentiation antigens gp100 and MART-1/Melan-A.

Epitope anal. indicated that two different epitopes derived from gp100 (154-162 and 280-288) and a single epitope from MART-1/Melan-A (27-35) were recognized by these CTL clones. The gp100-specific CTL clones were found to be significantly more sensitive to the culture conditions than the MART-1/Melan-A-specific CTL clones. In addn., the presence of excess peptide in the culture medium induced autokilling of the gp100-specific, but not the MART-1/Melan-A-specific CTL clones. These results demonstrate that, by careful preselection of melanoma cell lines and clones both for the induction of CTL line from patients' peripheral blood lymphocytes and subsequent cloning, it is possible to obtain a large no. of stable CTL clones even against such an inherently "difficult" differentiation antigen as gp100.

LANGUAGE: The authors identified circulating CD8+ T-cell populations specific AΒ for the tumor-assocd. antigens (TAAs) MART-1 (27-35) or tyrosinase (368-376) in 6 of 11 patients with metastatic melanoma using peptide/HLA-A\*0201 tetramers. These TAA-specific populations were of 2 phenotypically distinct types: one, typical for memory/effector T cells; the other, a previously undescribed phenotype expressing both naive and effector cell markers. This latter type represented >2% of the total CD8+ T cells in one patient, permitting detailed phenotypic and functional anal. Although these cells have many of the hallmarks of effector T cells, they were functionally unresponsive, unable to directly lyse melanoma target cells or produce cytokines in response to mitogens. In contrast, CD8+ T cells from the same patient were able to lyse EBV-pulsed target cells and showed robust allogeneic responses. Thus, the clonally

expanded TAA-specific population seems to have been selectively rendered anergic in vivo. Peptide stimulation of the TAA-specific T-cell populations in other patients failed to induce substantial upregulation of CD69 expression, indicating that these cells may also have functional defects, leading to blunted activation responses. Thus, systemic TAA-specific T-cell responses can develop de novo in cancer patients, but antigen-specific unresponsiveness may explain why such cells are unable to control tumor growth.

Immunogenic peptides of human tumor Ag have been used to generate antigen-specific CTL. However, the vast majority of these peptide-specific CTL clones are of low avidity and are peptide, but not tumor, reactive. Peptide-MHC tetramers have been shown to bind specific TCRs with sufficient affinity to be useful reagents for flow cytometry. In this paper the authors demonstrate that peptide-MHC tetramers can also be used to selectively identify high avidity tumor-reactive CTL and enrich, from a heterogeneous population, the subpopulation of peptide-reactive T cells that can lyse tumor targets. The melanoma proteins, MART-1 and gp100, were used to induce potentially tumor-reactive T cells, and the intensity of T cell staining by TCR binding of specific peptide-MHC tetramers was assessed. A range of fluorescence intensity was detected, and the magnitude of tetramer binding was correlated with T cell The population of peptide-reactive T cells was phenotypically similar with regard to expression of TCR and adhesion mols., suggesting that this differential avidity for tumor cells reflected differential affinity of the TCR for its peptide-MHC ligand. Sorting, cloning, and expansion of tetramerhigh CTL from a heterogeneous population of peptide-stimulated PBMCs enabled rapid selection of high avidity tumor-reactive CTL clones, which retained their functional and tetramerhigh phenotype on re-expansion. results demonstrate that the avidity of a  $T_{\underline{\ }}$  cell for its tumor target is due to the specific affinity of the TCR for its peptide-MHC ligand, that this interaction can be described using

melanoma antigen recognized by T lymphocytes, designated MART-1. This invention further relates to bioassays using the nucleic acid sequence, protein or antibodies of this invention to diagnose, assess or prognoses a mammal afflicted with melanoma or metastatic melanoma. This invention also provides immunogenic peptides derived from the MART-1 melanoma antigen and a second melanoma antigen designated gp100. This invention further provides immunogenic peptides derived from the MART-1 melanoma antigen or gp100 antigen which have been modified to enhance their immunogenicity. The proteins and peptides provided can serve as an immunogen or vaccine to prevent or treat melanoma.

substitutions were performed within the epitope and both HLA-A\*0201binding and CTL recognition were assayed. Anchor replacements towards the HLA-A\*0201 peptide-binding motif gave rise to peptides with higher HLA-A\*0201 binding capacity compared to the wild-type epitope. In addn., several of the gp100 154-162 epitope-analogs were more efficient at target-cell sensitization for lysis by anti-qp100 154-162 CTL compared to the wild-type epitope. These altered gp100 154-162 epitopes were subsequently tested for their capacity to induce CTL responses in vivo using HLA-A\*0201/Kb transgenic mice, and in vitro using HLA-A\*0201+ donor-derived lymphocytes. Interestingly, the peptide-specific CTL obtained, which were raised against the different gp100 154-162epitope-analogs, displayed cross-reactivity with target cells endogenously processing and presenting the native epitope. These data demonstrate that altered epitopes can be exploited to elicit native epitope-reactive CTL. The use of epitope-analogs with improved immunogenicity may contribute to the development of CTL-epitope based vaccines in viral disease and cancer.

TITLE:

TCR .beta.-chain variable region-driven selection and massive expansion of HLA class

I-restricted antitumor CTL lines from

HLA-A\*0201+ melanoma patients

AB Recognition of a given melanoma antigen (Ag) involves a limited array of T cell clones bearing a structurally defined TCR. The aim here was to verify whether this information can be used to isolate and expand such antitumor effectors from fresh lymphocyte populations. The authors found that 1-3 different TCR .beta.-chain variable (TCRBV) regions were expanded in 4-wk mixed lymphocyte-tumor cultures (MLTC) from 6 HLA-A\*0201+ melanoma patients, and that the T cells expressing the expanded TCRBV regions were involved in HLA class I-restricted lysis of the tumor. T cell activation by mAbs to MLTC-selected TCRBV region and CD28 resulted in large scale expansion (1-10.times.109 cells) of T cell lines, highly enriched for the expression of a single TCRBV region and for CD8+ T cells. The TCRBV-driven selection was equally effective when

applied to patients' or healthy donors' lymphocytes, and the T cell lines isolated from melanoma patients exerted HLA class I-restricted lysis of the autologous tumor. MLTC and TCRBV-selected lines recognized allogeneic melanomas sharing HLA-A and -B alleles with the autologous tumor, but only 2 of the HLA-A2-restricted lines were directed to a known peptide from melanoma-assocd. Ags. Single-strand conformation polymorphism anal. indicated a polyclonal compn. of both MLTC and TCRBV-selected lines, but expansion of clonotypes with identical CDR3 length was obsd. only in the MLTC lines. Thus, TCRBV-driven selection can be exploited to obtain large scale expansion of antitumor CTL lines from melanoma patients.

TITLE: Anti-melanoma cytotoxic T lymphocytes (CTL)

recognize numerous antigenic peptides having 'self' sequences: autoimmune nature of the

anti-melanoma CTL response

A line of tumor-infiltrating lymphocytes (660TIL) specifically lysed the autologous HLA-A2+ melanoma (660MEL) and also most A2+ melanoma cell lines. The authors immunopptd. A2 from a large no. (>1012) OF 660MEL cells, extd. naturally processed peptides, fractionated them by HPLC, screened the fractions for recognition by 660TIL, and found a single predominant and a minor peak of activity. Although too little was recovered of the major 660MEL peptide to establish its sequence, HPLC fingerprinting showed that it did not correspond to any of the known A2-assocd. melanoma peptides recognized by T cells, including peptides from tyrosinase, MART-1/Melan-A, gp100, and The major 660MEL antigenic peptide appears to be derived from MART-1/Melan-A but is neither AAGIGILTV nor ILTVILGVL nor any other MART-1/Melan-A peptide contg. the A2 consensus motif. The multiplicity of melanoma peptides recognized by CD8+ T cells, most of which are non-mutated (including most likely the present 660MEL peptide), suggests the existence of unknown mechanisms, perhaps similar to those operating in autoimmune disorders, whereby T cell that recognize normal self sequences become activated.

TITLE: Analogs of CTL epitopes with improved MHC

class-I binding capacity elicit anti-melanoma

CTL recognizing the wild-type epitope

The MHC class-I binding affinity of an epitope is an important AB parameter detg. the immunogenicity of the peptide-MHC complex. improve the immunogenicity of an epitope derived from melanocyte lineage-specific antigen gp100, we performed amino-acid substitutions within the epitope and assayed both HLA-A\*0201 binding and CTL recognition. Anchor replacements towards the HLA-A\*0201 peptide-binding motif gave rise to peptides with higher HLA-A\*0201binding capacity compared to the wild-type epitope. In addn., several of the gp100 154-162 epitope-analogs were more efficient at target-cell sensitization for lysis by anti-gp100 154-162 CTL compared to the wild-type epitope. These altered gp100 154-162 epitopes were subsequently tested for their capacity to induce CTL responses in vivo using HLA-A\*0201/Kb transgenic mice, and in vitro using HLA-A\*0201+ donor-derived lymphocytes. Interestingly, the peptide-specific CTL obtained, which were raised against the different gp100 154-162 epitope-analogs, displayed cross-reactivity with target cells endogenously processing and presenting the native epitope. These data demonstrate that altered epitopes can be exploited to elicit native epitope-reactive CTL. The use of epitope-analogs with improved immunogenicity may contribute to the development of CTL-epitope based vaccines in viral disease and

The gp100 melanoma-assocd. tumor antigen (Ag) was selected as a AB model system to study the diversity of human antitumor cytotoxic T cell responses. First, peptides corresponding to dominant gp100 HLA-A2.1-restricted CTL epitopes were tested using lymphocytes from normal volunteers and an in vitro priming protocol that uses peptide-pulsed dendritic cells as APCs and IL-7 and IL-10 as immune-enhancing cytokines. High CTL activity toward both peptide-pulsed target cells and gp100+ melanoma cells was obtained with 4 out of 5 peptides tested. Second, HLA-A2.1-binding peptides from gp100 that do not appear to represent CTL epitopes in melanoma patients were also tested for their capacity to induce CTL using the in vitro priming protocol. Three of 6 peptides tested induced CTL in lymphocytes from normal volunteers. One of these peptides was also immunogenic for lymphocytes derived from a melanoma patient in remission. Because these 3 CTL epitopes were not recognized in the natural immune response in melanoma patients but do appear as immunogens when peptides are used to induce the T cell response, they may be considered as typical "subdominant" epitopes. The results are discussed in the context of the usefulness of this approach to detail the immunol. potential of a given tumor-assocd. Ag and its relevance for the design of effective immune-based therapies.

The gp100 glycoprotein is a melanocytic lineage-specific antigen recognized by tumor-infiltrating lymphocytes, the adoptive transfer of which is assocd. with tumor regression in melanoma patients. In this study, peripheral blood mononuclear cells (PBMCs) were harvested from HLA-A2+ melanoma patients before and after immunization with G9-209 (ITDQVPFSY), G9-280 (YLEPGPVTA), or G9-154 (KTWGQYWQV) peptides in Incomplete Freund's Adjuvant and were tested for the ability to be sensitized in vitro using PBMCs pulsed with the native peptides. In addn., PBMCs from patients receiving the G9-209 or G9-280 peptide were stimulated in vitro with peptides modified at anchor residues to enhance binding to HLA-A2: G9-209/2M

(IMDQVPFSY) or G9-280-9V (YLEPGPVTV). In patients immunized with G9-209, a single in vitro restimulation with G9-209, a single in vitro restimulation with G9-209/2m resulted in the generation of specific antipeptide lymphocytes from 7 of 7 postimmune PBMCs and only 3 of 7 preimmune PBMCs. In patients immunized with G9-280, a single in vitro restimulation with G9-280/9V resulted in the generation of specific antipeptide lymphocytes from 5 of 6 postimmune PBMCs and 4 of 6 preimmune PBMCs. In almost all cases, CTLs raised against modified epitopes were capable of recognizing targets displaying the native nonamers. Several anti-G9-209 and anti-G9-209/2M CTLs also demonstrated specific lysis of, and specific IFN-.gamma. release in response to, gp100+ -established cell lines. Thus, using peptides modified to enhance immunogenicity for in vitro stimulation improved the sensitivity of immune monitoring of patients immunized with synthetic peptides. These results demonstrate that immunization with a peptide derived from a tumor-assocd. protein such as gp100 can provoke a measurable antitumor immune response in cancer patients.

Recognition of the melanoma Ag gp100 by tumor-infiltrating AB lymphocytes (TIL) in vitro has been correlated with tumor regression in patients with metastatic melanoma treated with the adoptive transfer of TIL plus IL-2. Three common gp100 epitopes have been identified that are recognized in the context of HLA-A2 by TIL from different patients: G9154 (KTWGQYWQV), G9209 (ITDQVPFSV), and G9280 (YLEPGPVTA). Upon stimulation with these peptides, melanoma-reactive CTL could be induced in vitro from PBL of some HLA-A2+ melanoma patients. However, numerous restimulations were required, and specific reactivity could not be generated in many patients. Therefore, to enhance the immunogenicity of gp100 peptides, amino acid substitutions were introduced into G9154, . G9209, and G9280 at HLA-A\*0201-binding anchor positions, but not at TCR contact residues, to increase peptide class I MHC-binding affinity. Several modified gp100 peptides bound with greater

affinity to HLA-A\*0201 than unmodified peptides and were recognized by TIL specific for the neutral epitopes. These peptides were used to sensitize PBL from HLA-A2+ melanoma patients in vitro using peptide-pulsed autologous PBMC as stimulators. After five weekly restimulations with either the native G9209 or G9280 peptide, melanoma-reactive CTL could only be induced from two of seven patients. However, amino acid substitutions in these peptides enabled the induction of melanoma-reactive CTL from all seven patients. These results suggest that modified gp100 peptides may be more immunogenic than the native epitopes, and may be useful in immunotherapy protocols for patients with melanoma.

Cellular immune responses to melanoma-assocd. Ags are the focus of ongoing studies aimed at developing immunotherapies for treatment of malignant melanoma. Melanoma predominantly affects Caucasians, a population in whom expression of HLA-A2 is prevalent. Among HLA-A2 subtypes, HLA-A\*0201 is widely expressed, and HLA-A\*0201-restricted, tumor-reactive CTL responses are well studied. We have obsd. in a group of melanoma patients an unexpectedly high frequency (.apprx.20%) of non-HLA-A\*0201 subtypes (\*0202, \*0204, and \*0205), and little is known regarding antimelanoma response profiles in patients expressing such subtypes. We analyzed non-HLA-A\*0201 peptide response profiles using HLA-A\*0201-restricted epitopes from melanoma Ags MART-1/Melan A and glycoprotein 100. Most of these peptides bound to the majority of subtypes tested with 50% inhibitory concns. less than 500 nM. Recognition of cells pulsed with different peptides (MART-1 G9154, and G9280 Flu M158-66) and expressing different subtype mols. by HLA-A\*0201-restricted CTL was limited to only a subset of non-HLA-A\*0201 mols., and the peptide/subtype complexes recognized varied among the effector populations tested. CTL responses elicited from PBL of patients and healthy donors expressing subtypes HLA-A\*0202 and HLA-A\*0205 suggested significant differences among HLA-A2 subtype function in

the context of melanoma Ag presentation. These observations imply the necessity of subtyping patients considered for peptide-based protocols and highlight the need for further study of melanoma-directed cellular responses among patients expressing non-HLA-A\*0201 subtypes.

The present invention provides a nucleic acid sequence encoding a melanoma antigen recognized by T lymphocytes, designated MART-1. This invention further reates to bioassays using the nucleic acid sequence, protein or antibodies of this invention to diagnose, assess or prognose a mammal afflicted with melanoma or metastatic

> Shears 308-4994 Searcher

melanoma. This invention also provides immunogenic peptides derived from the MART-1 melanoma antigen and a second melanoma antigen designated gp100. This invention further provides immunogenic peptides derived from the MART-1 melanoma antigen of gp100 antigen which have been modified to enhance their immunogenicity. proteins and peptides can serve as an immunogen or vaccine to prevent or treat melanoma. In example, cytotoxic T lymphocytes and culture of cell lines were prepd., immunogenic epitopes of MART-1 were characterized, and a second human melanoma antigen recognized by tumor infiltrating lymphocytes assocd. With in vivo tumor rejection was also identified. In addn., recognition of multiple epitopes in human melanoma antigen by tumor infiltrating lymphocytes, modified melanoma epitopes with improved immunogenicity, use of the improved epitopes as vaccine for treating melanoma in mammals, and use of lymphocytes sensitized to immunogenic peptides derived from melanoma antigens for therapeutically treating mammals afflicted with melanoma were demonstrated.

AB Gp100 is a melanocyte lineage-specific antigen recognized by tumor-infiltration lymphocytes whose adoptive transfer has been assocd. with tumor regression in patients with metastatic melanoma. The peripheral blood mononuclear cells of five melanoma patients were sensitized in vitro with synthetic peptides to elicit antigen-specific cytotoxic T lymphocyte (CTL) lines against four gp100 epitopes. These epitope-specific CTL lines were generated following weekly in vitro stimulation with the synthetic decamer G10476 (V-L-Y-R-Y-G-S-F-S-V) or the nonamers G9280 (Y-L-E-P-G-P-V-T-A), G9154 (K-T-W-G-Q-Y-W-Q-V), or G9209 (I-T-D-Q-V-P-F-S-V) pulsed onto autologous irradiated peripheral

blood mononuclear cells. These lines grew as long as 4 mo in culture in low-dose interleukin 2 (30 IU/mL) and exhibited antigen-specific, MHC class I-restricted lysis of peptide-pulsed T2 cells and HLA-A2+, gp100+ established melanoma cell lines. G10476and G9280-specific CTLs demonstrated specific release of granulocyte-macrophage-colony-stimulating factor and tumor necrosis factor .alpha. in response to T2 cells pulsed with relevant peptide, as well as to gp100+ melanoma cell lines. These results demonstrate that several peptides derived from the gp100 protein are presented on the surface of melanoma cells and are sufficiently immunogenic to generate, in vitro, potent CTLs capable of cytolysis and the secretion of cytokines. Therefore, for HLA-A2+ melanoma patients, these and possibly other gp100 peptides could represent good candidates for antigen-specific immunotherapy either singly or in a multivalent regimen.

#### IT 162558-08-9

RL: BAC (Biological activity or effector, except adverse); BSU (Biological study, unclassified); THU (Therapeutic use); BIOL (Biological study); USES (Uses)

(gp100-derived peptides stimulate cytotoxic T lymphocytes to release cytokines and lyse **melanoma** cells expressing gp100-derived peptides)

AB The present invention describes a melanoma associateed antigen known as gp100. Furthermore, peptides derived form said antigen are claimed. Gp100 and its peptides can be used in vaccines for the treatment of melanoma. Another aspect of the invention are host cells capable of expression of gp100 or the gp100-derived peptides. Furthermore, tumor infiltrating lymphocytes (TIL's) specifically recognizing gp100 are claimed, as are vaccines with these TIL's.

Cytotoxic T lymphocytes (CTL) reactive with human melanoma tumor cells occasionally display cross-reactivity with normal melanocytes. Previously, we identified the melanocyte lineage-specific antigen qp100 that is expressed by both melanoma cells and normal melanocytes, as a target antigen for tumor-infiltrating lymphocytes derived from a melanoma patient (TIL 1200). Here, we demonstrate that the oligoclonal HLA-A2.1-restricted TIL 1200 line is reactive with 2 distinct peptides derived from the gp100 protein. Apart from the peptide corresponding to gp100 amino acids 457-466, we identified the gp100 peptide 154-162 as a second epitope recognized by TIL 1200. A 100-fold lower concn. of this novel gp100 peptide was required for target-cell sensitization compared to peptide 457-466, indicating that the 154-162 peptide is the dominant gp100 epitope for TIL 1200. Together with the recently described gp100 280-288 epitope, 3 distinct CTL epitopes have now been identified in gp100, all presented in the context of HLA-A2.1. Therefore, gp100 is an attractive target antigen in the development of immuno-therapeutic protocols against melanoma.

Four of ten HLA-A2-restricted melanoma specific CTL that were AB derived from tumor-infiltrating lymphocytes (TIL) and administered to patients recognized the gp100 melanoma Ag and nine of ten recognized the MART-1 Ag. Adoptive transfer of the four gp100-reactive CTL, but not the other TIL, resulted in tumor regression when infused into autologous patients along with IL-2. Tumor regression was thus correlated with the recognition of gp100 by the administered T cells. To identify the epitopes recognized by these four gp100-reactive CTL, 169 peptides contg. HLA-A2.1 binding motifs were synthesized and screened for their recognition by TIL using cytotoxicity and IFN-.gamma. release assays. Five gp100 epitopes (two for TIL620, three for TIL550, one for TIL1143, and two for TIL1200) were recognized by CTL derived from different patients. Five of eight HLA-A2 binding melanoma epitopes (five gp100, one MART-1/Melan-A, two tyrosinase) had intermediate binding affinity to HLA-A2.1. These gp100 epitopes may be responsible for mediating tumor rejection in vivo and thus may be useful for the development of immunotherapies for patients with melanoma.

The glycoproteins recognized by monoclonal antibody (mAb) NKI-beteb are among the best diagnostic markers for human melanoma because their expression is restricted to melanocytic cells. Recently, the authors isolated a cDNA clone, termed gp100-c1, which confers immunoreactivity not only to mAb NKI-beteb, but also to two other mAbs used to diagnose malignant melanoma, HMB-50 and HMB-45. In this report, the authors demonstrate that gp100-c1 cDNA encodes glycoproteins of 100 kDa (gp100) and 10 kDa (gp10) which are recognized by these mAbs in human melanoma cells. The translation product deduced from the open reading frame persistent in gp100-c1 cDNA is highly homologous to another melanocyte-specific protein, Pmel17. Nucleotide sequence anal. of genomic DNA indicates that the transcripts corresponding to gp100 and Pmel17 cDNAs originate from a single gene via alternative splicing. In all normal and malignant melanocytic cells analyzed, gp100 and Pmel17 RNAs are simultaneously expressed.

Human melanoma cells, but not tumor cells of other histol. origin, express a unique membrane-assocd. glycoprotein, designated ME2-M, and secrete glycoprotein, designated Me20-S, defined by monoclonal antibody ME20. Here the authors report the isolation and characterization of a cDNA clone that when transfected into COS cells directs the expression of ME20-M and ME20-S. This cDNA contains an open reading frame which encodes a 661-amino-acid-long precursor that contains a 23-amino-acid signal peptide and a 26-amino-acid transmembrane domain, sepd. by a hydrophilic region contg. 5 potential Asn-linked and 14 predicted Pro-assocd., Thr-linked glycosylation sites. The transmembrane domain is followed by a carboxy-terminal 45-amino-acid putative intracellular domain rich in Ser residues. Anal. of ME20-M by amino acid sequencing identified the proteolytic processing site. Signal peptide cleavage occurs at the Thr-24-Lys-25 peptide bond of the precursor and results in the 637-amino-acid ME20-M with calcd. mol. wt. of 67,782. ME20-M is derived from a single 3.3- to 3.4-kb mRNA transcript that is expressed at varying levels in melanoma cell lines, correlating with immunofluorescence detn. of protein

expression. The amino acid sequence of the ME20 antigen deduced from the cDNA differs from the human neonatal melanocyte-specific Pmel 17 gene product by a single amino acid substitution and deletion of 7 amino acid residues, and it is 80 homologous with the bovine retinal pigment RPE1 cDNA. The obsd. differences in the sequence of the melanoma-derived and normal melanocyte-derived gene products may suggest that ME20-M is a unique tumor antigen or, alternatively, an oncofetal self-antigen, if the differences in the sequences are the result of a germ-line-encoded polymorphism.

IT 155422-80-3, Melanoma-associated ME20 antigen (Human clone HF12-2 gene ME20 precursor ME20-S) RL: BIOL (Biological study)

(amino acid sequence and signal peptide and C-terminal transmembrane domain and intracellular serine-rich domain and proteolytic processing site of)
